### ABSTRACT

Paper history: Received 16 August 2013 Received inrevised form 28 April 2014 Accepted 22 May 2014

Keywords: Gas Hydrates HYSYS Peng-Robinson Simulation Gas hydrates attracted worldwide attention due to their potential as huge energy resource in the recent decades. Effective parameters which influence the formation of hydrates are high pressure, low temperature and water presence. HYSYS software is one of the major simulators which is widely used in chemical and thermodynamic processes. This research was conducted to simulategas hydrate formation of Lavan-3 gas well and Salman gas field using the HYSYS software. The steady state simulation of hydrate formationwas performed by the Peng-Robinson equation of state. The predicted data were compared with experimental ones. It was concluded that HYSYS is able to predict hydrate formation with the average absolute error of less than 1%. Two novel correlations were also developed to estimate hydrate formation conditions for natural gas.

#### 1. INTRODUCTION

Clathrate hydrates form when small 'guest' molecules (< 0.9 nm) such as methane or carbon dioxide contact water at ambient temperatures (less than 300 K) and moderate pressures (more than 0.6 MPa). The single small guest molecules are encaged by hydrogen-bonded water cavities in the non-stoichiometric hydrates [1]. The water molecules in gas hydrates are linked to each other through hydrogen bonds to form a host lattice with polyhedral cavities that are large enough for small gas molecules such as methane, ethane, propane, carbon dioxide, and hydrogen sulphide [2]. There are three forms of hydrate structures: structure I for small molecules (such as methane and ethane), structure II for large molecules (such as propane and isobutene) and structure H. H hydrate requires a small molecule and a former agent such as methylcyclopentane. Most of H formers are not commonly found in the natural gas [3]. The cubic structure I predominates in the Earth's natural environments, and contains small guests (0.4–0.55 nm).

Please cite this article as: R. Davarnejad, J. Azizi, J. Azizi, Prediction of Gas Hydrate Formation using HYSYS Software, International Journal of Engineering (IJE), TRANSACTIONS C: Aspects Vol. 27, No. 9, (September 2014) 1325-1330

The cubic structure II generally occurs with larger guests (0.6–0.7 nm) in mostly man-made environments. The hexagonalstructure H may occur in either environment with mixtures of both small and large molecules (0.8–0.9 nm). The structure II was formed by the smallest hydrated molecules (such as Ar, Kr, O<sub>2</sub> and N<sub>2</sub>) with diameters less than 0.4 nm. There is one guest molecule within each cage in three structures. It is possible to have multiple-cage occupied with small guests such as hydrogen or noble gasesat unusual conditions (very high pressures) [4].

Recently natural gas hydrates are treated as a potential energy resource. Large amount of methane gas is trapped in hydrate reservoirs [5]. Gas production from a hydrate-capped gas reservoir is governed by a heat combination of transfer, fluid flow, thermodynamics of hydrate decomposition, and kinetic decomposition of hydrates [6]. Gas from hydrates is produced by the depressurization, thermal stimulation, and inhibitor injection [7]. According to Kvenvolden's research (1993), 1 m<sup>3</sup> of hydrate dissociation at ambient conditions forms 164 m<sup>3</sup> of natural gas and 0.8 m<sup>3</sup> of water.

There are several methods for hydrate formation prediction in natural gas systems [8, 9]. K-value method is a method which utilizes the vapor-solid equilibrium constants for hydrate formation [10]. Another method is obtained from the statistical calculations [11]. Katz (1945) also developed some plots based on the gas gravity [12]. The permissible expansion chart of natural gas can undergo without hydrate formation risk [13].

In this work, Peng-Robinson (PR) equation of state was chosen in the HYSYSsoftware (version 2006) to predict gas hydrate formation conditions. The predicted data were compared with the experimental onesobtained from the Salman gas field and Lavan-3 gas well.

#### 2. MATERIALS AND METHOD

2. 1. Reservoirs Description The lavan gas well was drilled in 1960s. Further drilling proved the existence of a gas field under Lavan Island where is at 18 km south of coastal line of the Persian Gulf (around 75.6 km<sup>2</sup>) with an estimated reserve of 6 TCF (Trillion Cubic Feet) of natural gas. The Salman field is at144 km south of Lavan Island in the Iranian section of Persian Gulf (located at Iran-Abu Dhabi border). The reservoirs compositions are shown in Tables 1 and 2. The related analyses are based on the UOP-9 and ASTM D-1945 methods.

2. 2. Applied Software HYSYS software (version 2006) was applied in the static mode. A suitable fluid package was chosen to satisfy all thermodynamic conditions indicated by laboratory results of gas hydrate formation. The schematic of this work is shown in Figure 1 [14].

2. 3. Equation of State (EOS) This essential first step will affect all subsequent tasks in developing accurate physical properties in the simulation. Indeed, the choice of the physical property models for a simulation can be one of the most important decisions for an engineer. Several factors need to be considered, and no single method can handle all systems. Four factors are consideredduring the property methods selection. They are nature of the properties of interest, composition of the mixture, pressure and temperature range, and availability of parameters.

Figures 2 and 3 are based on the four factors for property methods selection. They can be used when the chemical components and approximate temperature and pressure ranges are known [15].

The Peng-Robinson EOS is the most popular equation of state for natural gas systems in the petroleum industry [17]. For oil, gas and petrochemical applications, the Peng-Robinson EOS is generally recommended as the property package. According to the HYSYS manual, the Peng-Robinson equation of state supports the widest range of operating conditions for various systems. The Peng-Robinson and Soave-Redlich-Kwong equations of state generate some of the required equilibrium and thermodynamic properties [18, 19].

#### 3. RESULTS AND DISCUSSION

HYSYS predicted gas hydrate formation temperature at the same experimental pressure. Tables 3 and 4 compare the experimental data with the predicted ones. Figures 4and 5 show the hydrate formation temperature versus pressure. There is a good agreement between the predicted and experimental data. As shown in these figures, the predicted data were very close to the experimental ones in low temperatures. According to Equation (1), the absolute error for the present data was less than 1%.

$$Abs.error\% = \left|\frac{\text{Texp.-Thysys}}{\text{Texp.}}\right| \times 100$$
(1)

As shown in Figures 4 and 5, pressure slowly increased with temperature increment along the low temperatures (270-295 K) while it sharply increased with temperature enhancement along the high temperatures (295-305 K) during the hydrate formation. According to this,

temperature enhancement is a more suitable way than pressure reduction for prevention of hydrate formation. Two novel correlations were developed to estimate hydrate formation conditions. The correlations were validated in the range of 0-70 MPa and 270-310 K.

$$P = 10^{-7}T^6 - 2 \times 10^{-4}T^5 + 0.1353T^4 - 51.948T^3 + 11223T^2 - 10^6T + 6 \times 10^7$$
 (2)

$$P = -4 \times 10^{-6} T^{6} + 6.1 \times 10^{-3} T^{5} - 4.3718 t^{4} +$$

$$1676 t^{3} - 361327 t^{2} + 4 \times 10^{7} t - 2 \times 10^{9}$$

$$(3)$$

Equations (2) and (3) correlate the hydrate formation conditions for Lavan-3 gas well and Salman gas field based on the HYSYS data, respectively. For both correlations, R-square was very close to one ( $R^2$ =0.990).Figures 6 and 7 show the phase diagram for hydrate formation (pressure versus temperature). As shown in these figures, hydrate can form in the single and two-phase areas. Since hydrate formation needs the lower temperatures and pressures in the two-phase area, hydrate formation is harder in the single-phase area (gaseous phase). Therefore, the easiest way for prevention of hydrate formation is temperature enhancement and single-phase area production.

Figure 7. Depiction of phase envelope and flow assurance line for Salman gas field

#### 4. CONCLUSIONS

In this research, HYSYS software was applied to predict gas hydrate formation. There was a good agreement between the simulated and experimental results. The absolute average errors were less than 1%. Two proper correlations were developed based on the predicted data obtained from the HYSYS. It was concluded that the HYSYS is an accurate and rapid tool to predict hydrate formation. The results showed that hydrate formation was easy at low temperatures because it should be assisted by low pressures while hydrate formation was decreased with temperature enhancement due to the need for high pressures. However, hydrate could form in the single and two-phase areas but, hydrate formation was more probable in the two-phase area because it needed lower temperatures and pressures. Therefore, temperature enhancement can form the single-phase area (gaseous phase) and prevent hydrate formation.
